General Note: Nearly all studies of the impact of interventions designed to reduce exposure to carcinogens or to reduce the effect of these carcinogens have used surrogate short-term measures such as smoking rates and consumption of fruit and vegetables, rather than examining their impact on cancer prevalence or mortality. Given the long-term nature of the effect of such interventions on cancer rates, it seems unlikely that anything but surrogate end-points will be available in the immediate future.

| C1     | Tobacco consumption is associated with lung cancer, laryngeal cancer, oral cancer, oesophageal and gastric cancer and may be associated with cervical cancer and some types of leukaemia. A reduction in population levels of smoking may contribute to a lower incidence of lung, laryngeal and oral cancer. Taxation and similar fiscal and legislative measures can be used alongside interventions aimed at individuals to reduce cigarette consumption. Higher cigarette prices reduce cigarette consumption. However, the effect of increasing prices differs across demographic groups, a more marked reduction in consumption is shown with increasing price amongst women and young people. In the poorest groups, an increase in price produces significant hardship for those who do not curtail their consumption. No systematic reviews have been identified examining the effect on cancer rates of increasing tax on cigarettes. | a. NHS Executive. | C2 End advertising and promotion of cigarettes | Control of advertising is an effective intervention to place alongside interventions aimed at individuals to help reduce cigarette consumption.\(^a\)  
The ideal choice of policy for controlling advertising is to reduce the level of advertising and increase the level of counteradvertising. Research suggests that advertising bans lead to media substitution so a total ban on all forms of cigarette promotion is needed if bans are to be successful.\(^b\)  
| C3 Prohibit sale of cigarettes to youngsters and ensure enforcement | Interventions aimed at retailers to enforce the legal age limit on selling cigarettes to young people reduces their access to cigarettes but no evidence has been found that shows this affects smoking behaviour.\(^a\)  
Restricting access to cigarette vending machines limits access, but has not been shown to affect behaviour.\(^a\)  
Stronger regional, national and international strategies are required if restriction of youth access is to contribute to a reduction in smoking prevalence in this age group. Targeting retailers with educational programmes alone is less effective than combined education and enforcement (warnings or visits by police or health officials), but sustained effects require enforcement at least 4-6 times a year.\(^b\)  
| C4 Seek to ensure cheaper supplies of fruit and vegetables | Consumption of fresh fruit and vegetables is associated with a lower incidence of many cancers.\(^a\)  
No systematic reviews have been identified examining reducing the cost of fruit and vegetables and subsequent cancer rates. | a. American Institute for Cancer Research. Food Nutrition and the prevention of cancer. World Cancer Research Fund, 1997.

SYSTEMATIC REVIEWS OF RELEVANT EVIDENCE

The incidence of skin cancer has been increasing in the UK in recent years. The majority of skin cancers occur as a result of overexposure to ultraviolet light from the sun or an artificial source such as a sunbed, and are therefore preventable.

Preventative measures, such as sunscreens, are effective in avoiding overexposure of the skin to sunlight and may reduce the incidence of skin cancer. However, while health education programmes enhance knowledge of skin cancer, evidence that they change behaviour is very weak.\(^a\)

No systematic reviews have been identified which examine the effect of reducing skin exposure to ultraviolet light on subsequent rates of skin cancer.

CANCER: Personal behaviour

**POLICY**

C17 (cont)Fund health education campaigns to provide reliable and objective information on the health risks of smoking, poor diet and too much sun (cont)

**SYSTEMATIC REVIEWS OF RELEVANT EVIDENCE**

Adults found the most successful interventions for increasing fruit and vegetable consumption were those that were part of a multi-component programme. Successful interventions included education directed at behavioural change, were over a longer time period with multiple contacts made with participants, and used a message specifically targeted to fruit and vegetables rather than nutrition in general.\(^a\)

**Body mass/Physical activity/Dietary fat intake:**

There is a modest inverse association between body mass index and the risk of breast cancer\(^i\) and also some evidence that exercise is associated with a reduced risk of early onset breast cancer.\(^j\) Research has shown that women are much less physically active than men.\(^k\)

Dietary fat reduction can result in a lowering of serum oestradiol levels and may offer an approach to breast cancer prevention.\(^l\)

A review on low fat diets for reducing obesity is underway.\(^m\)

No systematic reviews have been identified relating interventions to reduce dietary fats/obesity/increase physical activity and cancer rates.

**Other dietary factors:**

No association has been detected between artificial sweetener consumption and bladder cancer in humans even though saccharin has been found to be carcinogenic in rats.\(^n\)

No association between a high intake of linoleic acid and breast, colorectal or prostate cancer has been found in humans, despite animal experiments indicating that linoleic acid is required to promote growth of artificially induced tumors in rodents.\(^o\)

There is no support for the hypothesis that calcium protects against colorectal cancer\(^p\) or that a high coffee consumption protects against colorectal cancer.\(^q\)

Government and National Players can:

**C25** Encourage doctors, dentists, nurses and other health professionals to give advice on prevention (cont)

**SYSTEMATIC REVIEWS OF RELEVANT EVIDENCE**

Patient education and counselling contribute to behaviour change for primary prevention of disease, some techniques, particularly self-monitoring, and using several communication channels, eg media plus personal communication, having the greatest effect.\(^9\)

**Advice on alcohol intake:**

Brief interventions in primary care, including assessment of alcohol intake and provision of information and advice, may be used to reduce alcohol consumption in those with consumption levels above recommended levels. Evidence suggests alcohol consumption can be reduced by up to 20% in people with raised alcohol consumption. Brief interventions are as effective as more expensive specialist treatment in this context.\(^b\)

**Advice on smoking cessation:**

Advice given by GPs can be effective in reducing smoking.\(^c\) Training health professionals increases the degree to which they offer anti-smoking interventions, and their effectiveness in doing so.\(^d\)

**Advice on weight reduction:**

There is evidence that health professionals can improve the organisation of care for obese people, and weight reduction may reduce the risk of breast and endometrial cancer as well as many other diseases.\(^e\)

**Advice on prevention and cancer rates:**

A review of methods to implement prevention in primary care is underway.\(^f\) Other reviews are examining the use of physician reminders in prevention.\(^g\) However no reviews have been identified that assess the effects of advice on prevention on cancer rates.

**Other areas of advice related to prevention:**

There is evidence of a small increase in the risk of breast cancer in women taking the oral contraceptive pill and for ten years after they cease to take it. This factor should be taken into account when making decisions about using

independently by two readers, one of whom is a radiologist.d

There is continuing uncertainty about the effects of breast cancer screening in women under 50.f

There is however, no evidence that breast self-examination is effective.g

Colorectal cancer:

Colorectal cancer screening using faecal occult blood tests can reduce mortality from colorectal cancer. Annual screening is more effective than biennial screening.h

Colonoscopic surveillance should be offered to patients with long standing ulcerative colitis.i A review of screening for colorectal cancer in people with all types of inflammatory bowel disease is underway.j

Prostate cancer:

Evidence suggests that screening for prostate cancer is not presently justified as the screening tests are not sufficiently accurate, available treatments have not been adequately evaluated and, given the slow growing nature of prostate tumours, outcome may be as good as without active intervention.k

Ovarian cancer:

Evidence suggests that routine screening for ovarian cancer is not presently justified in women, with or without a family history of ovarian cancer, since the available tests are insensitive and can raise anxiety without any evidence that they reduce mortality or morbidity.l

Lung cancer:

Screening for lung cancer is not presently justified as there is little evidence that it reduces mortality or morbidity rates and there is some evidence that it causes harm.m

A further review on the effectiveness of screening for lung cancer is underway.n

### SYSTEMATIC REVIEWS OF RELEVANT EVIDENCE

Evidence suggests that one third of women with breast cancer symptoms delay seeking help for 3 or more months and that delays in diagnosing breast cancer of 3-6 months are associated with lower survival.

No systematic reviews have been identified on the effect of interventions to reduce delay in diagnosis on survival rates.

Outcomes in cancer treatment can be improved by concentrating care in the hands of specialists, although there is wide variability in outcome across the UK. Treatment within randomised controlled trials may also result in better outcomes.

Centralisation of cancer services can make access for people in rural areas more difficult. There is some weak evidence that shared outreach is safe and can make specialist care more accessible to outlying patients.

After primary treatment is complete, routine intensive hospital follow up after cancer treatment has not been shown to improve outcome. GP-led follow-up with access to specialist care appears to be effective and acceptable to both patients and GPs.

Effective palliative care by home care teams allows patients to stay at home longer, which is preferred by most patients and is the least expensive option for the NHS.

Systematic reviews of the effects of strategies for dealing with common problems in palliative care are being prepared and will inform the guidelines in the management of palliation.

C34

**Diagnosis and staging:**

Careful evaluation of patients with suspected and diagnosed cancer is necessary to inform treatment decisions.

**Cervical cancer:**

Computed tomography and magnetic resonance imaging provide more detailed information for clinical evaluation of invasive cervical cancer, but no reviews were identified assessing the impact of diagnostic methods on treatment or outcomes.
# CANCER: Services interventions

## POLICY

**C34**  
(cont) Ensure rapid specialist treatment for cancers when they are diagnosed (cont)

## SYSTEMATIC REVIEWS OF RELEVANT EVIDENCE

### Head and neck cancer:

Computed tomography examination is superior to physical examination in the detection of lymph nodes in the neck. However, no reviews have been identified on the impact of diagnostic methods on treatment or outcomes.

### Lung cancer:

Computed tomography and radionuclide imaging have a high negative predictive value, but no reviews have been identified on the influence of diagnostic tests on survival.

### Melanoma:

Both the ABCD and 7-point checklists appear to be sensitive diagnostic tests that can help physicians differentiate between benign and malignant moles.

### Urological cancer:

There is evidence that macroscopic haematuria is a risk marker for urological cancer. However no reviews have been identified that examined the impact of diagnostic tests on survival or other outcomes.

### Breast cancer:

The speed and cost-effectiveness of definitive diagnosis for suspected breast cancer can be substantially improved by the routine and consistent use of the “Triple assessment” (a combination of clinical examination, mammography and fine-needle aspiration cytology).

## Treatment:

### Prostate cancer:

In the management of early prostate cancer one review concluded that radiotherapy is superior to radical prostatectomy, but other evidence found that survival with any of watchful waiting, radiotherapy or radical prostatectomy is relatively high with no significant difference in mortality between the three treatments.

**POLICY**

C34 (cont) Ensure rapid specialist treatment for cancers when they are diagnosed. (cont)

**SYSTEMATIC REVIEWS OF RELEVANT EVIDENCE**

Conservative management is a reasonable treatment option for men with localised disease.

No one radiotherapy technique is has been found to be superior.

Evidence suggests that maximal androgen blockade (MAB) for advanced prostate cancer produces a modest overall and cancer-specific survival at 5 years (from 0-5%) but is associated with increased adverse events and reduced quality of life.

Lung cancer:

Multiple drug chemotherapy in advanced and disseminated non-small cell lung cancer reduces mortality at six months and improves quality of life. Cisplatin-based chemotherapy combinations improve survival rates, but has unpleasant side effects.

Prophylactic granulocyte colony-stimulating factor (G-CSF) does not affect mortality, but does significantly reduce the incidence of neutropenic fever in patients receiving chemotherapy for small cell lung cancer.

A review on chemotherapy for extensive small cell lung cancer is underway.

A review of maintenance chemotherapy for small cell lung cancer found that trials showing poor outcomes were of poor methodological quality. The authors thus concluded that maintenance therapy may be associated with some survival advantage, particularly in patients with limited disease and those responding completely to cyclophosphamide and in cases of objective response to multi-drug regimens.

POLICY

Ensure rapid specialist treatment for cancers when they are diagnosed (cont)

SYSTEMATIC REVIEWS OF RELEVANT EVIDENCE

Vulval cancer:

Evidence from a review of surgical treatments for early squamous cell carcinoma of the vulva concludes that radical local excision, ipsilateral lymph node dissection in lateral tumors and triple incision technique are safe treatment options for early vulvar cancer. However, superficial groin node dissection results in an excess of groin recurrences compared to a full femoro-inguinal groin node dissection.

Breast cancer:

When managing ductal carcinoma in situ of the breast, lumpectomy followed by radiotherapy is an appropriate alternative for most patients. The use of lumpectomy alone in selected patients remains controversial.

A review on post-operative radiotherapy for ductal carcinoma in situ is in preparation.

Sentinel lymph node biopsy reflects the status of the axilla in 97% of cases and has a false negative rate of 5%.

Patients treated with breast conserving surgery have comparable survival rates to patients allocated to mastectomy. Mastectomy without adjuvant radiation appears to be inferior to breast conserving therapy for node positive patients.

It is important to select treatment on an individual basis taking into account factors such as the risk of local recurrence and the likely impact of disfigurement. Evidence suggests that women who had breast conservation had a more favourable image of themselves, but the evidence on other parameters is inconclusive and the quality of the relevant evidence is poor.

Evidence suggests that in early breast cancer, radiotherapy produces a two-thirds reduction in local recurrence of the disease, and would be expected to produce an absolute increase in 20-year survival of about 2-4% were it not for the long-term hazards associated with the therapy. The average hazard reduces this 20-year survival benefit in young women and reverses it in older women. This review is ongoing.

A review on immunotherapy for early breast cancer is in preparation, but the evidence from a previous review is that immunotherapy does not confer any

**SYSTEMATIC REVIEWS OF RELEVANT EVIDENCE**

- Survival benefit.1
- Adjuvant systemic therapy in breast cancer using tamoxifen, ovarian ablation, or chemotherapy, improves survival and reduces recurrence rates in many women and is cost-effective.2
- Evidence strongly favours some years of adjuvant tamoxifen for a wide range of women with early breast cancer, at least in terms of recurrence and survival, and the balance of the known long-term benefits and risks.1 This review is ongoing.3

There is evidence that ablation of functioning ovaries in early breast cancer in women aged under 50 significantly improves long-term survival, at least in the absence of chemotherapy. Further randomised evidence is needed on the additional effects of ovarian ablation in the presence of other adjuvant treatments, and to assess the relevance of hormone-receptor measurements.3

Some months of adjuvant polychemotherapy typically produces an absolute improvement of about 7-11% in 10-year survival for women aged under 50 at presentation with early breast cancer, and of about 2-3% for those aged 50-69 (unless their prognosis is likely to be extremely good even without such treatment). Treatment decisions involve consideration not only of improvements in cancer recurrence and survival but also of adverse side-effects of treatment, no recommendations are offered as to who should or should not be treated.4 This review is ongoing.5

Evidence suggests that combined cytotoxic and endocrine adjuvant therapies might be the most effective use of available treatments for most, if not all, patients with operable breast cancer.4

A review on follow-up strategies for women treated for early breast cancer is in preparation.1 Evidence from a consensus statement suggests that mammography at one or two-year intervals, depending on the type of primary surgery and age of the patient, is the most effective follow-up after primary treatment. Evidence does not call for the routine use of any other instrumental test.6

C34 (cont) Ensure rapid specialist treatment for cancers when they are diagnosed (cont)

**SYSTEMATIC REVIEWS OF RELEVANT EVIDENCE**

Chemotherapy and hormonal therapy for women with metastatic breast cancer, offers a modest survival benefit but there is no evidence on the impact on quality of life.1 The effectiveness of tamoxifen appears similar to ovarian ablation in premenopausal women with metastatic breast cancer.a

Strong evidence supports the use of bisphosphonates to reduce both skeletal events (osteoporosis, osteolysis and pathologic fractures) and pain in multiple myeloma and in breast cancer patients with metastatic bone disease. Evidence also suggests bisphosphonates are useful as part of a pain management program for bone metastases from carcinoma of the breast, lung, and prostate, and for symptomatic myeloma. The bisphosphonates appear to be well tolerated.v

Colorectal Cancer:

In early colorectal cancer surgery, care must be taken to remove tumour involvement at the circumferential margins, since such involvement is associated with high recurrence rates of colorectal cancer.a Routine pre-operative radiotherapy can improve outcome in patients with rectal cancer except in cases where there are low (<10%) local recurrence rates.a

In surgery for colorectal cancer, intra-operative technical problems and

#### SYSTEMATIC REVIEWS OF RELEVANT EVIDENCE

- Postoperative strictures were more common with stapled anastomoses than hand sewn anastomoses, but there were no differences detected in other outcomes.\(^b\)

- The use of prolonged (>3 months) systemic chemotherapy, particularly if established early on, can improve survival in early operable colorectal cancer.\(^c\)

- Evidence suggests that adjuvant 5-fluorouracil (5-FU) chemotherapy (with or without other cytotoxic drugs) delivered through the portal vein for about 1 week directly after surgery in patients with colorectal cancer may produce an absolute improvement in 5 year survival of around 5% percent. This evidence, however, is not strong.\(^d\)

- Continuous infusion of 5-FU is superior to bolus 5-FU when used in advanced colorectal cancer.\(^e\)

- Modulation of 5-FU by methotrexate doubles the response rate compared to 5-FU alone and yields a small improvement in survival.\(^f\)

- Evidence shows the benefit of biomodulation of 5-fluorouracil by leucovorin.\(^g\)

- Hepatic artery infusion chemotherapy increases survival over systemic chemotherapy in patients with colorectal cancer that has metastasized to the liver.\(^h\)

- Intensive follow-up detects more recurrent cancers at a stage amenable to curative resection, resulting in an improvement in survival.\(^i\)

Leukaemia:
No cures based on systemic therapy have been found for patients with cutaneous T-cell lymphomas, although both single and combined chemotherapeutic agents produce high response rates. No evidence has been found to recommend one particular agent over another, but systemic therapy can be considered effective and palliative.\(^a\)

Conservative treatment strategies for chronic lymphatic leukaemia produce the best level of survival. This would be deferred chemotherapy for most patients with early-stage disease, and single-agent chlorambucil as the first line of treatment for most patients with advanced disease. No evidence of benefit from early inclusion of an anthracycline has been found.\(^b\)

For patients with Philadelphia chromosome positive chronic myeloid leukaemia, alpha-interferon increases survival compared with standard chemotherapy.\(^c\) There is insufficient evidence of the effect in other types of chronic myeloid leukaemia.\(^d\) A new review of alpha-interferon for chronic myeloid leukaemia is underway.\(^d\)

Intensive reinduction chemotherapy produces a small absolute improvement in long term survival in children with acute lymphoblastic leukaemia.\(^e\)

CNS radiotherapy appears to result in cognitive deficits in children treated for acute lymphoblastic leukaemia.\(^f\)

Evidence suggests that induction regimens based on idarubicin achieve better remission rates and better overall survival than those based on daunorubicin.\(^g\)

Haematological cancer:
Combined radiotherapy and chemotherapy for Hodgkin's disease has a significantly inferior survival compared to chemotherapy alone.\(^a\) In early stage Hodgkin's Disease patients, less intensive primary treatment, particularly a reduction in radiotherapy fields, appears to achieve similar survival rates to more intensive treatment.\(^b\)

Early stage Hodgkin's disease in children is mostly curable but that there is not enough evidence to show which treatments are best in the long term.\(^c\)

CANCER: Additional evidence

Drinking water

Chlorination by-products in drinking water are associated with an increased risk of bladder and rectal cancer.\(^a\)

A systematic review is being carried out to assess effects of drinking water fluoridation.\(^b\)

Treatment of side-effects associated with cancer treatments

Several reviews have examined effective treatment for side-effects in cancer patients.

Antifungal therapy is effective in cancer patients with neutropenia.\(^a\)

Fluoroquinolones plus other antibiotics significantly reduce the occurrence of gram negative and positive bacteremia without affecting the incidence of morbidity or mortality in patients receiving chemotherapy.\(^b\)

Quinolone prophylaxis substantially reduces the incidence of various infection-related outcomes but not deaths in cancer patients who are neutropenic following chemotherapy.\(^c\)

P6 acupuncture seems to be an effective antiemetic technique.\(^d\)

5-HT3 antiemetics have similar efficacy to high dose metoclopramide, with fewer side-effects.\(^e\)

Reviews of the effects of non-surgical interventions for late radiation cystitis and proctitis in patients who have received radical radiotherapy to the pelvis are underway.\(^f\)

There is some evidence that ice chips prevent mucositis in patients receiving chemotherapy. None of the other prophylactic agents in the review prevented mucositis although prophylactic antifungal agents reduced the incidence of oral candidiasis.\(^g\)

A review of treatment of oral mucositis in patients receiving chemotherapy is underway.\(^h\)

Another review is being prepared assessing the effects of treatment of oral candidiasis for cancer patients receiving chemotherapy and/or radiotherapy.\(^i\)

The value of conservative management strategies for post prostatectomy incontinence remains uncertain.\(^j\)
